Feel free to use these slides verbatim, or to modify them to fit your own needs. If you make use of a significant portion of these slides in your own lecture, please include this message, or a link to our web site: <http://www.mmds.org>

# Community Detection in Graphs

CS246: Mining Massive Datasets  
Jure Leskovec, Stanford University  
<http://cs246.stanford.edu>

# Networks & Communities

- We often think of networks being organized into **modules, clusters, communities**:

# Goal: Find Densely Linked Clusters

# Non-overlapping Clusters

Network

Adjacency matrix

# Micro-Markets in Sponsored Search

- Find micro-markets by partitioning the query-to-advertiser graph:

[Andersen, Lang: Communities from seed sets, 2006]

# Movies and Actors

- Clusters in Movies-to-Actors graph:

[Andersen, Lang: Communities from seed sets, 2006]

# Twitter & Facebook

## ■ Discovering social circles, circles of trust:

[McAuley, Leskovec: Discovering social circles in ego networks, 2012]

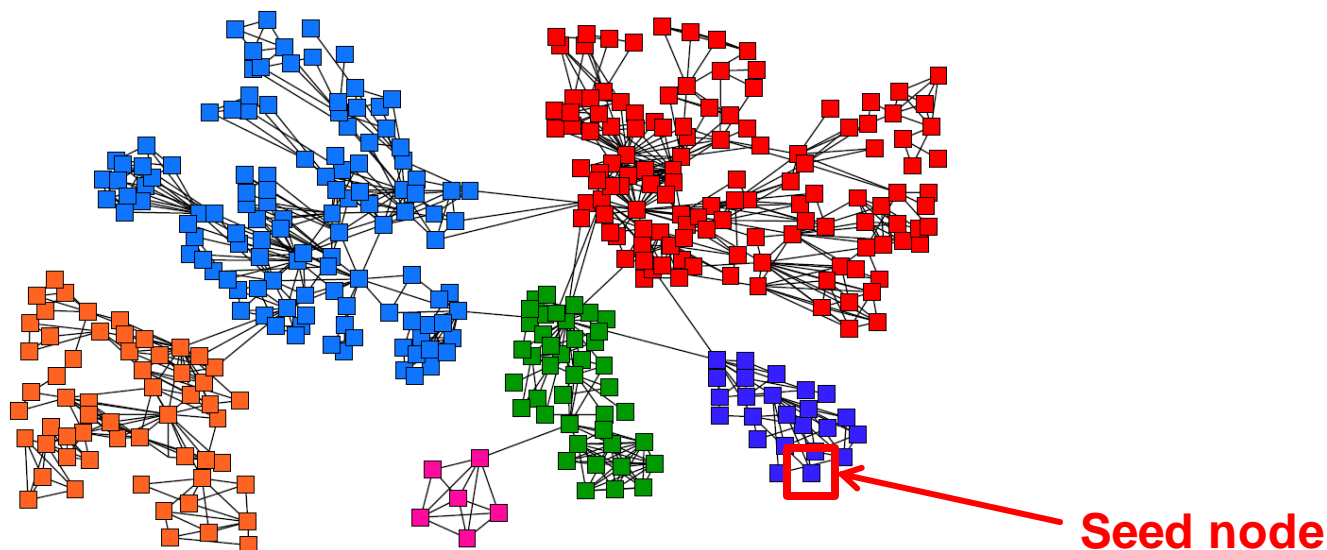

# The Setting

- **Graph is large**
  - **Assume the graph fits in main memory**
    - For example, to work with a 200M node and 2B edge graph one needs approx. 16GB RAM.
  - But the graph is too big for running anything more than linear time algorithms.
- **We will cover a PageRank based algorithm for finding dense clusters.**
  - **The runtime of the algorithm will be proportional to the cluster size (not the graph size!).**

# Idea: Seed Nodes

- **Discovering clusters based on seed nodes**
  - **Given:** Seed node  $s$
  - Compute (approximate) **Personalized PageRank (PPR)** around node  $s$  (teleport set= $\{s\}$ )
  - Idea is that if  $s$  belongs to a nice cluster, the random walk will get **trapped** inside the cluster

# Seed Node: Intuition

## ■ Algorithm outline:

- Pick a seed node  $s$  of interest
- Run **PPR** with teleport set =  $\{s\}$
- Sort the nodes by the decreasing **PPR** score
- **Sweep** over the nodes and find **good clusters**

# What makes a good cluster?

- Undirected graph  $G(V, E)$ :

- Partitioning task:

- Divide vertices into 2 disjoint groups  $A, B = V \setminus A$

- Question:

- How can we define a “good” cluster in  $G$ ?

# What makes a good cluster?

- **What makes a good cluster?**
  - Maximize the number of within-cluster connections
  - Minimize the number of between-cluster connections

# Graph Cuts

- Express cluster quality as a function of the “edge cut” of the cluster
- **Cut:** Set of edges (edge weights) with only one node in the cluster:

$$\text{cut}(A) = \sum_{i \in A, j \notin A} w_{ij}$$

**Note:** This works for weighted and unweighted (set all  $w_{ij}=1$ ) graphs

# Cut Score

- **Partition quality: Cut score**
  - Quality of a cluster is the weight of connections pointing outside the cluster
- **Not so uncommon case:**

- **Problem:**
  - Only considers external cluster connections
  - Does not consider internal cluster connectivity

# Graph Partitioning Criteria

## ■ Criterion: **Conductance**:

Connectivity of the group to the rest of the network relative to the density of the group

$$\phi(A) = \frac{|\{(i, j) \in E; i \in A, j \notin A\}|}{\min(\text{vol}(A), 2m - \text{vol}(A))}$$

$\text{vol}(A)$ : total weight of the edges with at least one endpoint in  $A$ :  $\text{vol}(A) = \sum_{i \in A} d_i$

■  $\text{Vol}(A) = 2 * \text{\#edges inside } A + \text{\#edges pointing out of } A$

## ■ **Why use conductance?**

■ Produces more balanced partitions

$m$ ... number of edges of the graph  
 $d_i$ ... degree of node  $i$   
 $E$ ... edge set of the graph

# Example: Conductance Score

$$\phi = 2/4 = 0.5$$

$$\phi = 6/92 = 0.065$$

# Algorithm Outline: Sweep

## ■ Algorithm outline:

- Pick a seed node  $s$  of interest
- Run **PPR** w/ teleport= $\{s\}$
- Sort the nodes by the decreasing **PPR** score
- **Sweep** over the nodes and find good clusters

## ■ Sweep:

- Sort nodes by decreasing PPR score  $r_1 > r_2 > \dots > r_n$
- For each  $i$  compute  $\phi(A_i = \{u_1, \dots, u_i\})$
- **Local minima** of  $\phi(A_i)$  correspond to good clusters

# Computing the Sweep

- The whole Sweep curve can be computed in **linear time**:

- For loop over the nodes
- Keep hash-table of nodes in a set  $A_i$

- To compute  $\phi(A_{i+1}) = \text{Cut}(A_{i+1}) / \text{Vol}(A_{i+1})$

- $\text{Vol}(A_{i+1}) = \text{Vol}(A_i) + d_{i+1}$

- $\text{Cut}(A_{i+1}) = \text{Cut}(A_i) + d_{i+1} - 2\#(\text{edges of } u_{i+1} \text{ to } A_i)$

# Computing PPR

## ■ How to compute Personalized PageRank (PPR) without touching the whole graph?

- Power method won't work since each single iteration accesses all nodes of the graph:

$$\mathbf{r}^{(t+1)} = \beta \mathbf{M} \cdot \mathbf{r}^{(t)} + (1 - \beta) \mathbf{a}$$

At index  $S$

- $\mathbf{a}$  is a teleport vector:  $\mathbf{a} = [0 \dots 0 \mathbf{1} 0 \dots 0]^T$
- $\mathbf{r}$  is the personalized PageRank vector

## ■ Approximate PageRank (AKA PageRank-Nibble)

[Andersen, Chung, Lang, '07]

- A fast method for computing approximate Personalized PageRank (**PPR**) with teleport set  $S=\{s\}$
- **ApproxPageRank( $s, \beta, \epsilon$ )**
  - $s$  ... seed node
  - $\beta$  ... teleportation parameter
  - $\epsilon$  ... approximation error parameter

# Approximate PPR: Overview

## ■ Approximate PPR on undirected graph

- **Lazy random walk**, which is a variant of a random walk that stays put with probability  $1/2$  at each time step, and walks to a random neighbor the other half of the time:

$$r_u^{(t+1)} = \frac{1}{2} r_u^{(t)} + \frac{1}{2} \sum_{i \rightarrow u} \frac{1}{d_i} r_i^{(t)}$$

$d_i \dots$  degree of  $i$

- Keep track of **residual PPR score**  $q_u = p_u - r_u^{(t)}$ 
  - **Residual**  $q_u$ : how well is PPR score  $p_u$  of  $u$  is approximated
  - $p_u \dots$  is the “true” PageRank of node  $u$
  - $r_u^{(t)} \dots$  is PageRank estimate of node  $u$  at around  $t$

If **residual**  $q_u$  of node  $u$  is too big  $\frac{q_u}{d_u} \geq \epsilon$  then **push the walk further** (distribute some of residual  $q_u$  to all  $u$ 's neighbors along outgoing edges), else we don't touch the node

# Towards approximate PPR

## ■ A different way to look at PageRank:

[Jeh&Widom. *Scaling Personalized Web Search*, 2002]

$$\mathbf{p}_\beta(\mathbf{a}) = (1 - \beta)\mathbf{a} + \beta \mathbf{p}_\beta(\mathbf{M} \cdot \mathbf{a})$$

- $\mathbf{p}_\beta(\mathbf{a})$  is the true PageRank vector with teleport parameter  $\beta$ , and teleport vector  $\mathbf{a}$
- $\mathbf{p}_\beta(\mathbf{M} \cdot \mathbf{a})$  is the PageRank vector with teleportation vector  $\mathbf{M} \cdot \mathbf{a}$ , and teleportation parameter  $\beta$ 
  - where  $\mathbf{M}$  is the stochastic PageRank transition matrix
  - **Notice:**  $\mathbf{M} \cdot \mathbf{a}$  is one step of a random walk

# Towards approximate PPR

- Proving:  $p_{\beta}(a) = (1 - \beta)a + \beta p_{\beta}(M \cdot a)$ 
  - We can break this probability into two cases:
    - Walks of length 0, and
    - Walks of length longer than 0
  - The probability of length 0 walk is  $1 - \beta$ , and the walk ends where it started, with walker distribution  $a$
  - The probability of walk length  $>0$  is  $\beta$ , and then the walk starts at distribution  $a$ , takes a step, (so it has distribution  $Ma$ ), then takes the rest of the random walk to with distribution  $p_{\beta}(Ma)$ 
    - Note that we used the memoryless nature of the walk: After we know the location of the second step of the walk has distribution  $Ma$ , the rest of the walk can forget where it started and behave as if it started at  $Ma$ . This proves the equation.

# “Push” Operation

residual PPR score  $q_u = p_u - r_u$

- Idea:  $a$ ...teleport vector
  - $r$ ... approx. PageRank,  $q$ ... its residual PageRank
  - Start with trivial approximation:  $r = 0$  and  $q = a$
  - Iteratively **push** PageRank from  $q$  to  $r$  until  $q$  is small
- Push: 1 step of a lazy random walk from node  $u$ :

$Push(u, r, q)$ :

$$r' = r, \quad q' = q$$

$$r'_u = r_u + (1 - \beta)q_u$$

$$q'_u = \frac{1}{2}\beta q_u$$

for each  $v$  such that  $u \rightarrow v$ :

$$q'_v = q_v + \frac{1}{2}\beta \frac{q_u}{d_u}$$

return  $r', q'$

$1 - \beta$ ...teleport prob

Update  $r$

**Do 1 step of a walk:**

Stay at  $u$  with prob.  $\frac{1}{2}$

Spread remaining  $\frac{1}{2}$  fraction of  $q_u$  as if a single step of random walk were applied to  $u$

# Intuition Behind Push Operation

- If  $q_u$  is large, this means that we have underestimated the importance of node  $u$
- Then we want to take some of that residual ( $q_u$ ) and give it away, since we know that we have too much of it
- So, we keep  $\frac{1}{2}\beta q_u$  and then give away the rest to our neighbors, so that we can get rid of it
  - This correspond to the spreading of  $\frac{1}{2}\beta q_u/d_u$  term
- Each node wants to keep giving away this excess PageRank until all nodes have no or a very small gap in excess PageRank

*Push*( $u, r, q$ ):

$$r' = r, \quad q' = q$$

$$r'_u = r_u + (1 - \beta)q_u$$

$$q'_u = \frac{1}{2}\beta q_u$$

for each  $v$  such that  $u \rightarrow v$ :

$$q'_v = q_v + \frac{1}{2}\beta \frac{q_u}{d_u}$$

return  $r', q'$

# Approximate PPR

## ■ **ApproxPageRank( $S, \beta, \epsilon$ ):**

Set  $\mathbf{r} = \vec{0}$ ,  $\mathbf{q} = [0 \dots 0 \ 1 \ 0 \dots 0]$

**While**  $\max_{u \in V} \frac{q_u}{d_u} \geq \epsilon$ :  At index  $S$

Choose any vertex  $u$  where  $\frac{q_u}{d_u} \geq \epsilon$

**Push( $u, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r}' = \mathbf{r}, \mathbf{q}' = \mathbf{q}$$

$$r'_u = r_u + (1 - \beta)q_u$$

$$q'_u = \frac{1}{2} \beta q_u$$

For each  $v$  such that  $u \rightarrow v$ :

$$q'_v = q_v + \frac{1}{2} \beta q_u / d_u$$

$$\mathbf{r} = \mathbf{r}', \mathbf{q} = \mathbf{q}'$$

**Return  $\mathbf{r}$**

$\mathbf{r}$  ... PPR vector

$r_u$  ... PPR score of  $u$

$\mathbf{q}$  ... residual PPR vector

$q_u$  ... residual of node  $u$

$d_u$  ... degree of  $u$

Update  $\mathbf{r}$ : Move  $(1 - \beta)$  of the prob. from  $\mathbf{q}_u$  to  $\mathbf{r}_u$

**1 step of a lazy random walk:**

- Stay at  $u$  with prob.  $\frac{1}{2}$
- Spread remaining  $\frac{1}{2} \beta$  fraction of  $\mathbf{q}_u$  as if a single step of random walk were applied to  $u$

# Example: $\beta = 0.5$

**ApproxPageRank( $S, \beta, \epsilon$ ):**

Set  $\mathbf{r} = \vec{0}$ ,  $\mathbf{q} = [0 \dots 0 \ 1 \ 0 \dots 0]$

**while**  $\max_{u \in V} \frac{q_u}{d_u} \geq \epsilon$ :

Choose any vertex  $\mathbf{u}$  where  $\frac{q_u}{d_u} \geq \epsilon$

**Push( $\mathbf{u}, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r}' = \mathbf{r}, \quad \mathbf{q}' = \mathbf{q}$$

$$\mathbf{r}'_u = \mathbf{r}_u + (1 - \beta) q_u$$

$$\mathbf{q}'_u = \frac{1}{2} \beta q_u$$

For each  $\mathbf{v}$  such that  $(\mathbf{u}, \mathbf{v}) \in E$ :

$$\mathbf{q}'_v = \mathbf{q}_v + \frac{1}{2} \beta \frac{q_u}{d_u}$$

Update  $\mathbf{r} = \mathbf{r}', \quad \mathbf{q} = \mathbf{q}'$

**return**  $\mathbf{r}$

**s a b c**

**Init:**

$$\mathbf{r} = [0, 0, 0, 0]$$

$$\mathbf{q} = [1, 0, 0, 0]$$

**Push( $\mathbf{s}, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r} = [.5, 0, 0, 0]$$

$$\mathbf{q} = [.25, .08, .08, .08]$$

**Push( $\mathbf{s}, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r} = [.62, 0, 0, 0]$$

$$\mathbf{q} = [.06, .10, .10, .10]$$

**Push( $\mathbf{a}, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r} = [0.62, .05, 0, 0]$$

$$\mathbf{q} = [.09, .03, .10, .10]$$

**Push( $\mathbf{b}, \mathbf{r}, \mathbf{q}$ ):**

$$\mathbf{r} = [0.62, .05, .05, 0]$$

$$\mathbf{q} = [.09, .05, .03, .10]$$

....

$$\mathbf{r} = [0.57, 0.19, 0.14, 0.09]$$

# Observations (1)

## ■ Runtime:

- Approximate PageRank computes PPR in time  $\left(\frac{1}{\varepsilon(1-\beta)}\right)$  with residual error  $\leq \varepsilon$ 
  - Power method would take time  $O\left(\frac{\log n}{\varepsilon(1-\beta)}\right)$

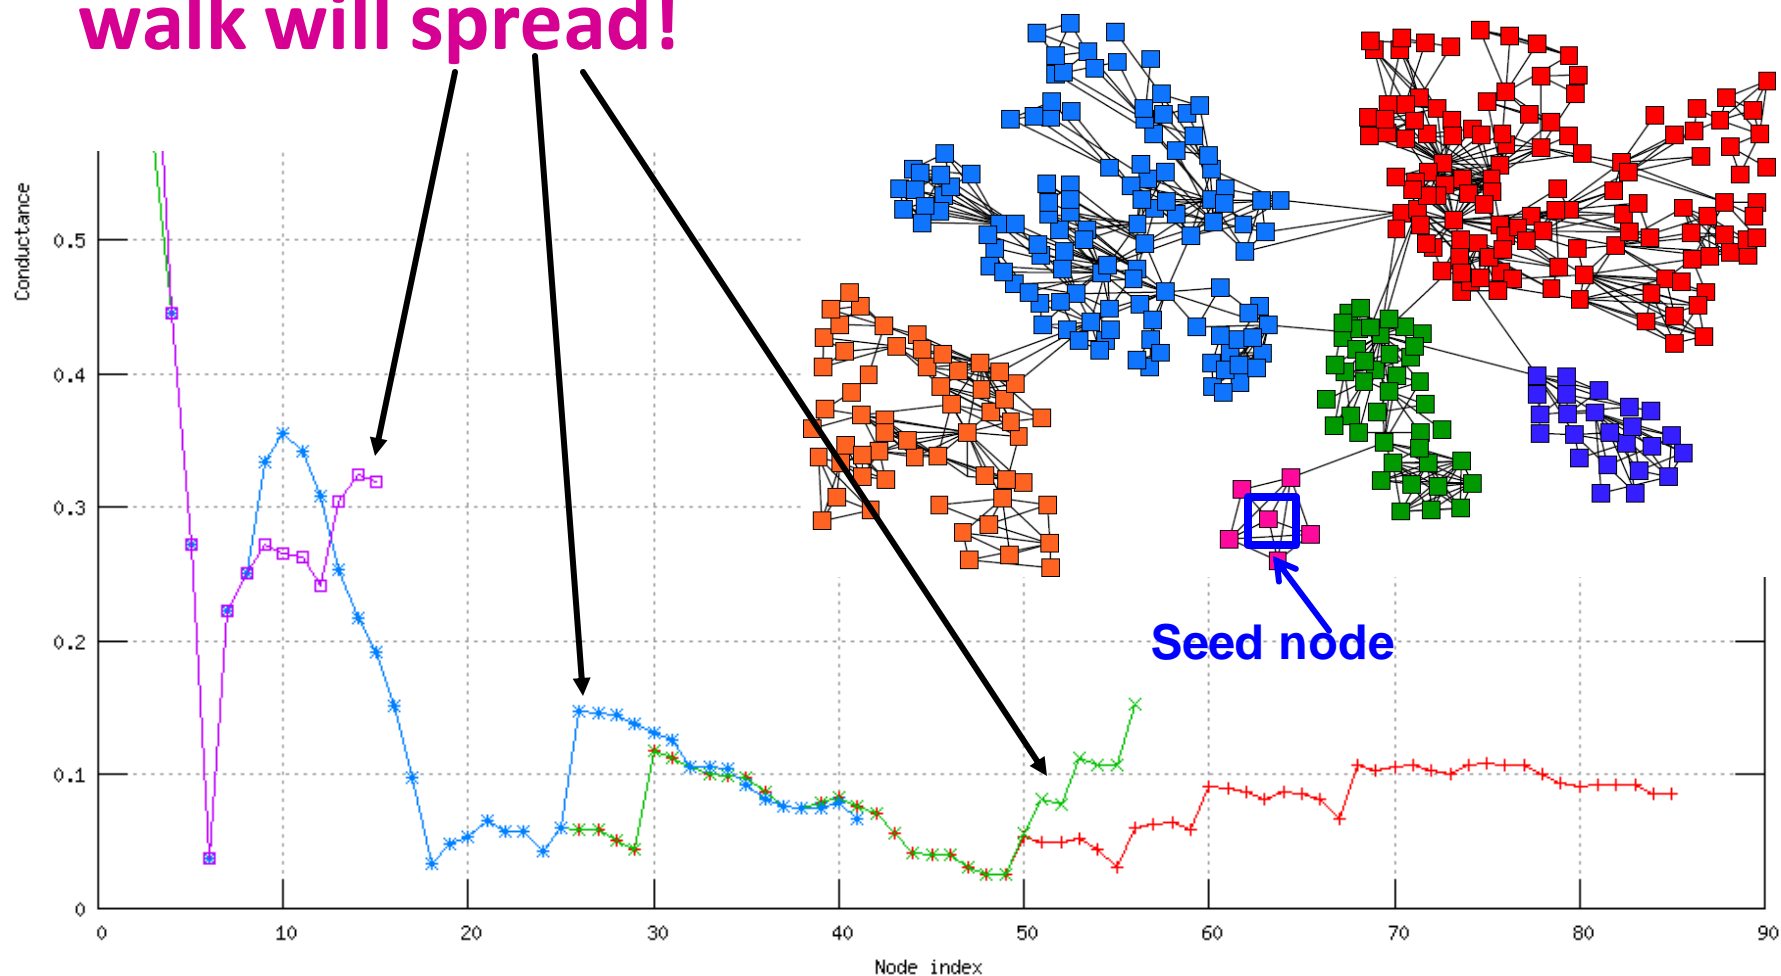

## ■ Graph cut approximation guarantee:

- If there exists a cut of conductance  $\phi$  and volume  $k$  then the method finds a cut of conductance  $O(\sqrt{\phi / \log k})$
- Details in [Andersen, Chung, Lang. *Local graph partitioning using PageRank vectors*, 2007]

<http://www.math.ucsd.edu/~fan/wp/localpartfull.pdf>

# Observations (2)

- The smaller the  $\epsilon$  the farther the random walk will spread!

# Observations (3)

[Andersen, Lang: Communities from seed sets, 2006]

# Example

# Summary of Approx PPR Alg.

## ■ Algorithm summary:

- Pick a seed node  $s$  of interest
- Run **PPR** with teleport set =  $\{s\}$
- Sort the nodes by the decreasing **PPR** score
- **Sweep** over the nodes and find good clusters

# Motif-Based Spectral Clustering

# Motif-based Spectral Clustering

- What if we want our clustering based on other patterns (not edges)?

Small subgraphs (motifs, graphlets) are building blocks of networks [Milo et al., '02]

# Motif-based spectral clustering

Network:

Motif:

# Re-define Conductance for Motifs

## ■ Generalize cuts and volumes to motifs

$vol(S) = \#(\text{edge end-points in } S)$

$vol_M(S) = \#(\text{motif end-points in } S)$

$$\phi(S) = \frac{\#(\text{edges cut})}{vol(S)}$$

$$\phi_M(S) = \frac{\#(\text{motifs cut})}{vol_M(S)}$$

**Optimize motif  
conductance**

[Benson et al., '16]

# Motif-based Clustering

## ■ Three basic stages:

### ■ 1) Pre-processing

- $W_{ij}^{(M)} = \# \text{ times } (i, j) \text{ participates in the motif}$

### ■ 2) Approximate PageRank

- Same as before but on weighted  $W^{(M)}$

### ■ 3) Sweep

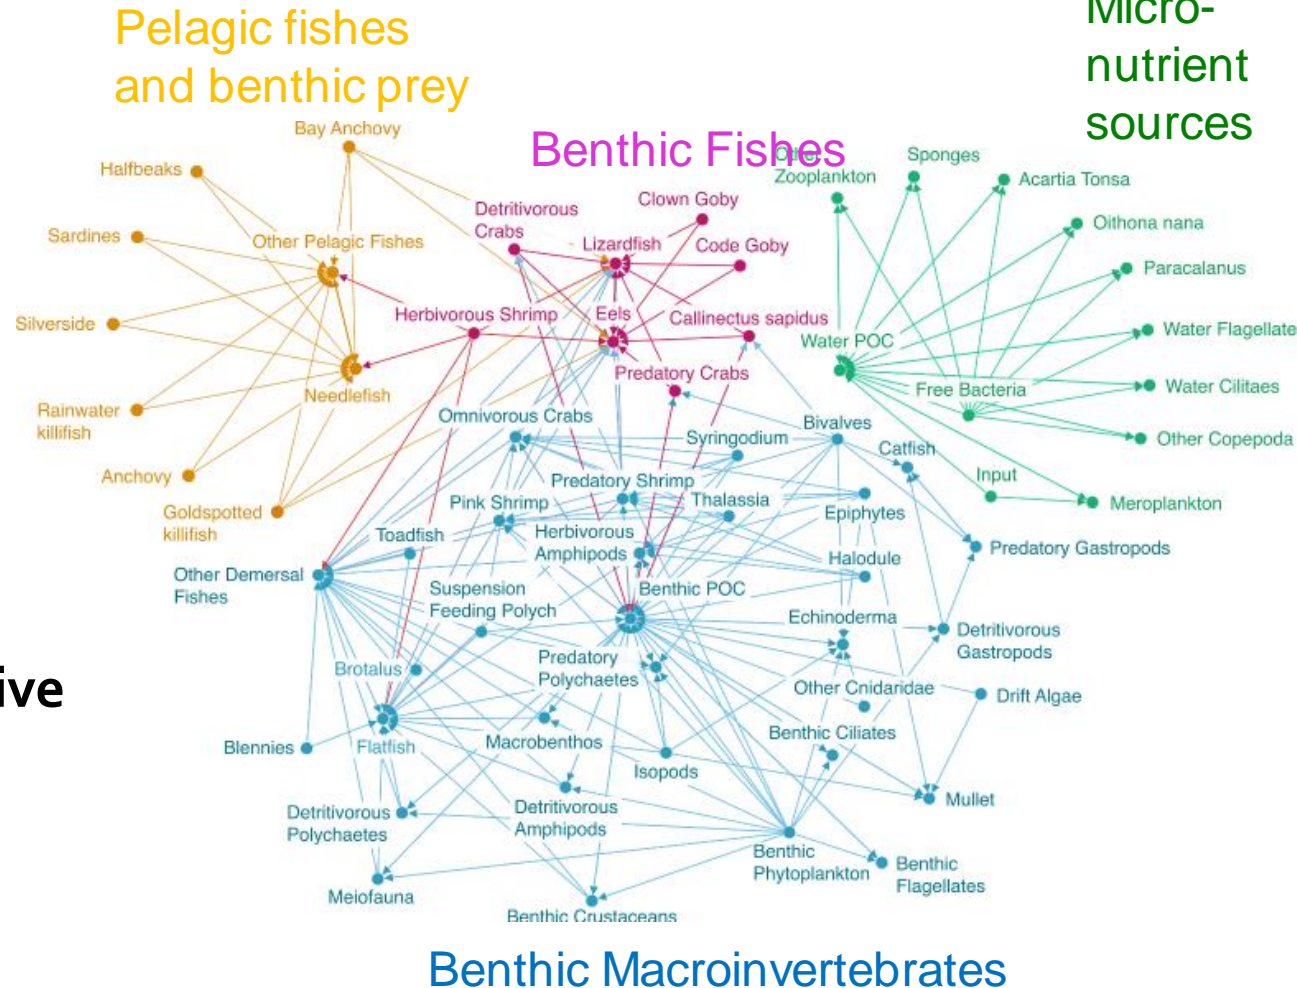

- Same as before

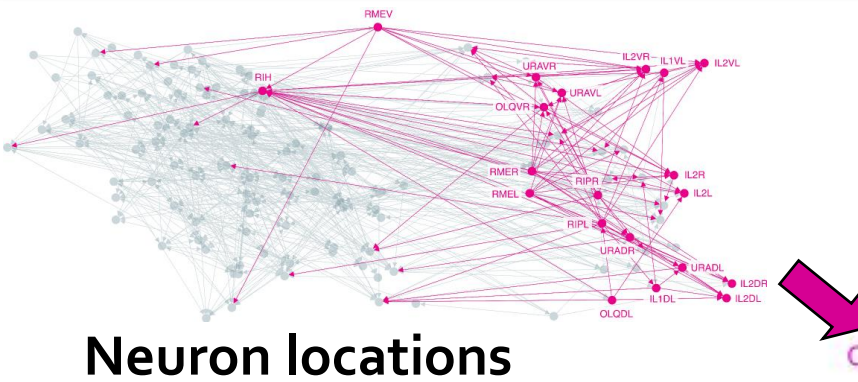

# Motif-based Clustering of a Food Web

Use multiple  
eigenvectors or recursive  
bi-partitioning to get  
multiple clusters

# Motif Clustering of a Neural Network

“Bi-fan” motif known to be important in neural networks  
[Milo et al., '02]

- Ring motor (RME\*) neurons act as inputs
- Inner labial sensory (IL2\*) neurons are the destinations
- URA neurons act as intermediaries

# Modularity Maximization

# Network Communities

- **Communities:** sets of tightly connected nodes

- Define: **Modularity  $Q$**

- A measure of how well a network is partitioned into communities
- Given a partitioning of the network into groups  $s \in S$ :

$$Q \propto \sum_{s \in S} [ \underbrace{(\# \text{ edges within group } s) - (\text{expected } \# \text{ edges within group } s)} ]$$

Need a null model!

# Null Model: Configuration Model

- Given real  $G$  on  $n$  nodes and  $m$  edges, construct rewired network  $G'$

- Same degree distribution but random connections

- Consider  $G'$  as a **multigraph**

- The expected number of edges between nodes

$i$  and  $j$  of degrees  $k_i$  and  $k_j$  equals to:  $k_i \cdot \frac{k_j}{2m} = \frac{k_i k_j}{2m}$

- The expected number of edges in (multigraph)  $G'$ :

$$\blacksquare = \frac{1}{2} \sum_{i \in N} \sum_{j \in N} \frac{k_i k_j}{2m} = \frac{1}{2} \cdot \frac{1}{2m} \sum_{i \in N} k_i \left( \sum_{j \in N} k_j \right) =$$

$$\blacksquare = \frac{1}{4m} 2m \cdot 2m = m$$

Note:

$$\sum_{u \in V} k_u = 2m$$

# Modularity

- **Modularity of partitioning  $S$  of graph  $G$ :**

- $Q \propto \sum_{s \in S} [ (\# \text{ edges within group } s) - (\text{expected } \# \text{ edges within group } s) ]$

- $Q(G, S) = \underbrace{\frac{1}{2m}}_{\text{Normalizing const.: } -1 < Q < 1} \sum_{s \in S} \sum_{i \in s} \sum_{j \in s} \left( A_{ij} - \frac{k_i k_j}{2m} \right)$

Normalizing const.:  $-1 < Q < 1$

$A_{ij} = 1$  if  $i \rightarrow j$ ,  
0 else

- **Modularity values take range  $[-1, 1]$**

- It is positive if the number of edges within groups exceeds the expected number
- $Q$  greater than **0.3-0.7** means **significant community structure**

# Modularity: 2 Defs

$$Q(G, S) = \frac{1}{2m} \sum_{s \in S} \sum_{i \in s} \sum_{j \in s} \left( A_{ij} - \frac{k_i k_j}{2m} \right)$$

**Equivalently modularity can be written as:**

$$Q = \frac{1}{2m} \sum_{ij} \left[ A_{ij} - \frac{k_i k_j}{2m} \right] \delta(c_i, c_j)$$

- $A_{ij}$  represents the edge weight between nodes  $i$  and  $j$ ;
- $k_i$  and  $k_j$  are the sum of the weights of the edges attached to nodes  $i$  and  $j$ , respectively;
- $2m$  is the sum of all of the edge weights in the graph;
- $c_i$  and  $c_j$  are the communities of the nodes; and
- $\delta$  is an indicator function

**Idea: We can identify communities by maximizing modularity**

# Louvain Algorithm

# Louvain Algorithm

- **Greedy algorithm** for community detection
  - $O(n \log n)$  run time
- Supports weighted graphs
- Provides hierarchical communities
- Widely utilized to **study large networks** because:
  - Fast
  - Rapid convergence
  - High modularity output (i.e., “better communities”)

Network and communities:

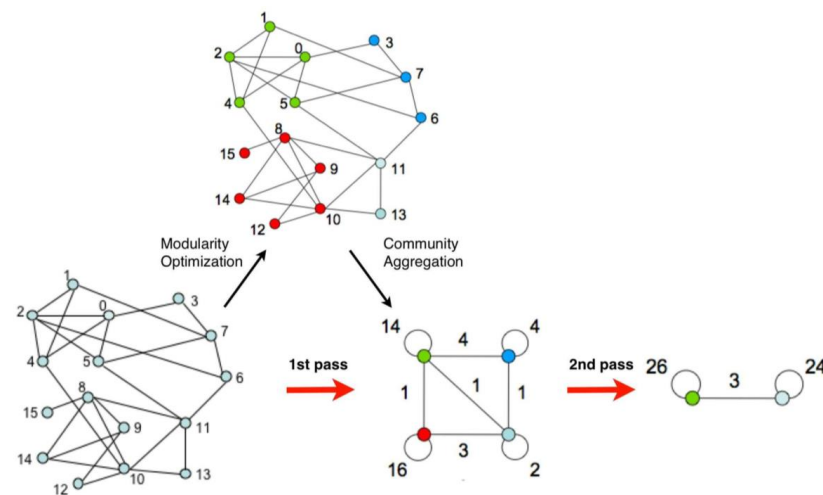

Dendrogram:

# Louvain Algorithm: At High Level

- Louvain algorithm **greedily maximizes** modularity
- **Each pass is made of 2 phases:**
  - **Phase 1:** Modularity is **optimized** by allowing only local changes to node-communities memberships
  - **Phase 2:** The identified communities are **aggregated** into super-nodes to build a new network
- **Goto Phase 1**

The passes are repeated **iteratively** until no increase of modularity is possible.

# Louvain: 1<sup>st</sup> phase (Partitioning)

- Put each node in a graph into a **distinct community** (one node per community)
- For each node  $i$ , the algorithm performs two calculations:
  - Compute the modularity delta ( $\Delta Q$ ) when putting node  $i$  into the community of some neighbor  $j$
  - Move  $i$  to a community of node  $j$  that yields the largest gain in  $\Delta Q$
- **Phase 1 runs until no movement yields a gain**

This first phase stops when a local maxima of the modularity is attained, i.e., when no individual node move can improve the modularity.

Note that the output of the algorithm depends on the order in which the nodes are considered.

Research indicates that the ordering of the nodes does not have a significant influence on the overall modularity that is obtained.

# Louvain: Modularity Gain

What is  $\Delta Q$  if we move node  $i$  to community  $C$ ?

$$\Delta Q(i \rightarrow C) = \left[ \frac{\Sigma_{in} + k_{i,in}}{2m} - \left( \frac{\Sigma_{tot} + k_i}{2m} \right)^2 \right] - \left[ \frac{\Sigma_{in}}{2m} - \left( \frac{\Sigma_{tot}}{2m} \right)^2 - \left( \frac{k_i}{2m} \right)^2 \right]$$

■ where:

- $\Sigma_{in}$ ... sum of link weights between nodes in  $C$
  - $\Sigma_{tot}$ ... sum of all link weights of nodes in  $C$
  - $k_{i,in}$ ... sum of link weights between node  $i$  and  $C$
  - $k_i$ ... sum of all link weights (i.e., degree) of node  $i$
- Also need to derive  $\Delta Q(D \rightarrow i)$  of taking node  $i$  out of community  $D$ .
  - And then:  $\Delta Q = \Delta Q(i \rightarrow C) + \Delta Q(D \rightarrow i)$

$\Sigma_{in}$ :

$\Sigma_{tot}$ :

# Louvain: Modularity Gain

## More in detail:

Modularity contribution  
after merging node  $i$

Modularity contribution  
before merging node  $i$

$$\Delta Q(i \rightarrow C) = \left[ \frac{\Sigma_{in} + k_{i,in}}{2m} - \left( \frac{\Sigma_{tot} + k_i}{2m} \right)^2 \right] - \left[ \underbrace{\frac{\Sigma_{in}}{2m} - \left( \frac{\Sigma_{tot}}{2m} \right)^2}_{\text{Modularity of } C} - \underbrace{\left( \frac{k_i}{2m} \right)^2}_{\text{Modularity of } i} \right]$$

By applying the Modularity definition:

$$Q = \frac{1}{2m} \sum_{ij} \left[ A_{ij} - \frac{k_i k_j}{2m} \right] \delta(c_i, c_j)$$

# Louvain: 2<sup>nd</sup> phase (Restructuring)

- The communities obtained in the first phase are contracted into **super-nodes**, and the network is created accordingly:
  - Super-nodes are connected if there is at least one edge between the nodes of the corresponding communities
  - The weight of the edge between the two super-nodes is the sum of the weights from all edges between their corresponding communities
- **Phase 1 is then run on the super-node network**

# Louvain Algorithm

## Algorithm 1: Sequential Louvain Algorithm

**Input:**  $G = (V, E)$ : graph representation.

**Output:**  $C$ : community sets at each level;

$Q$ : modularity at each level.

**Var:**  $\hat{c}$ : vertex  $u$ 's best candidate community set.

```

1 Loop outer
2    $C \leftarrow \{\{u\}\}, \forall u \in V$ ;
3    $\Sigma_{in}^c \leftarrow \sum w_{u,v}, e(u,v) \in E, u \in c \text{ and } v \in c$ ;
4    $\Sigma_{tot}^c \leftarrow \sum w_{u,v}, e(u,v) \in E, u \in c \text{ or } v \in c$ ;
5   // Phase 1.
6   Loop inner
7     for  $u \in V$  and  $u \in c$  do
8       // Find the best community for vertex  $u$ .
9        $\hat{c} \leftarrow \operatorname{argmax}_{\forall c', \exists e(u,v) \in E, v \in c'} \Delta Q_{u \rightarrow c'}$ ; Modularity gain
10      if  $\Delta Q_{u \rightarrow \hat{c}} > 0$  then
11        // Update  $\Sigma_{tot}$  and  $\Sigma_{in}$ .
12         $\Sigma_{tot}^{\hat{c}} \leftarrow \Sigma_{tot}^{\hat{c}} + w(u)$ ;  $\Sigma_{in}^{\hat{c}} \leftarrow \Sigma_{in}^{\hat{c}} + w_{u \rightarrow \hat{c}}$ ;
13         $\Sigma_{tot}^c \leftarrow \Sigma_{tot}^c - w(u)$ ;  $\Sigma_{in}^c \leftarrow \Sigma_{in}^c - w_{u \rightarrow c}$ ;
14        // Update the community information.
15         $\hat{c} \leftarrow \hat{c} \cup \{u\}$ ;  $c \leftarrow c - \{u\}$ ;
16      if No vertex moves to a new community then
17        exit inner Loop;

```

Halting criterion for 1<sup>st</sup> Phase

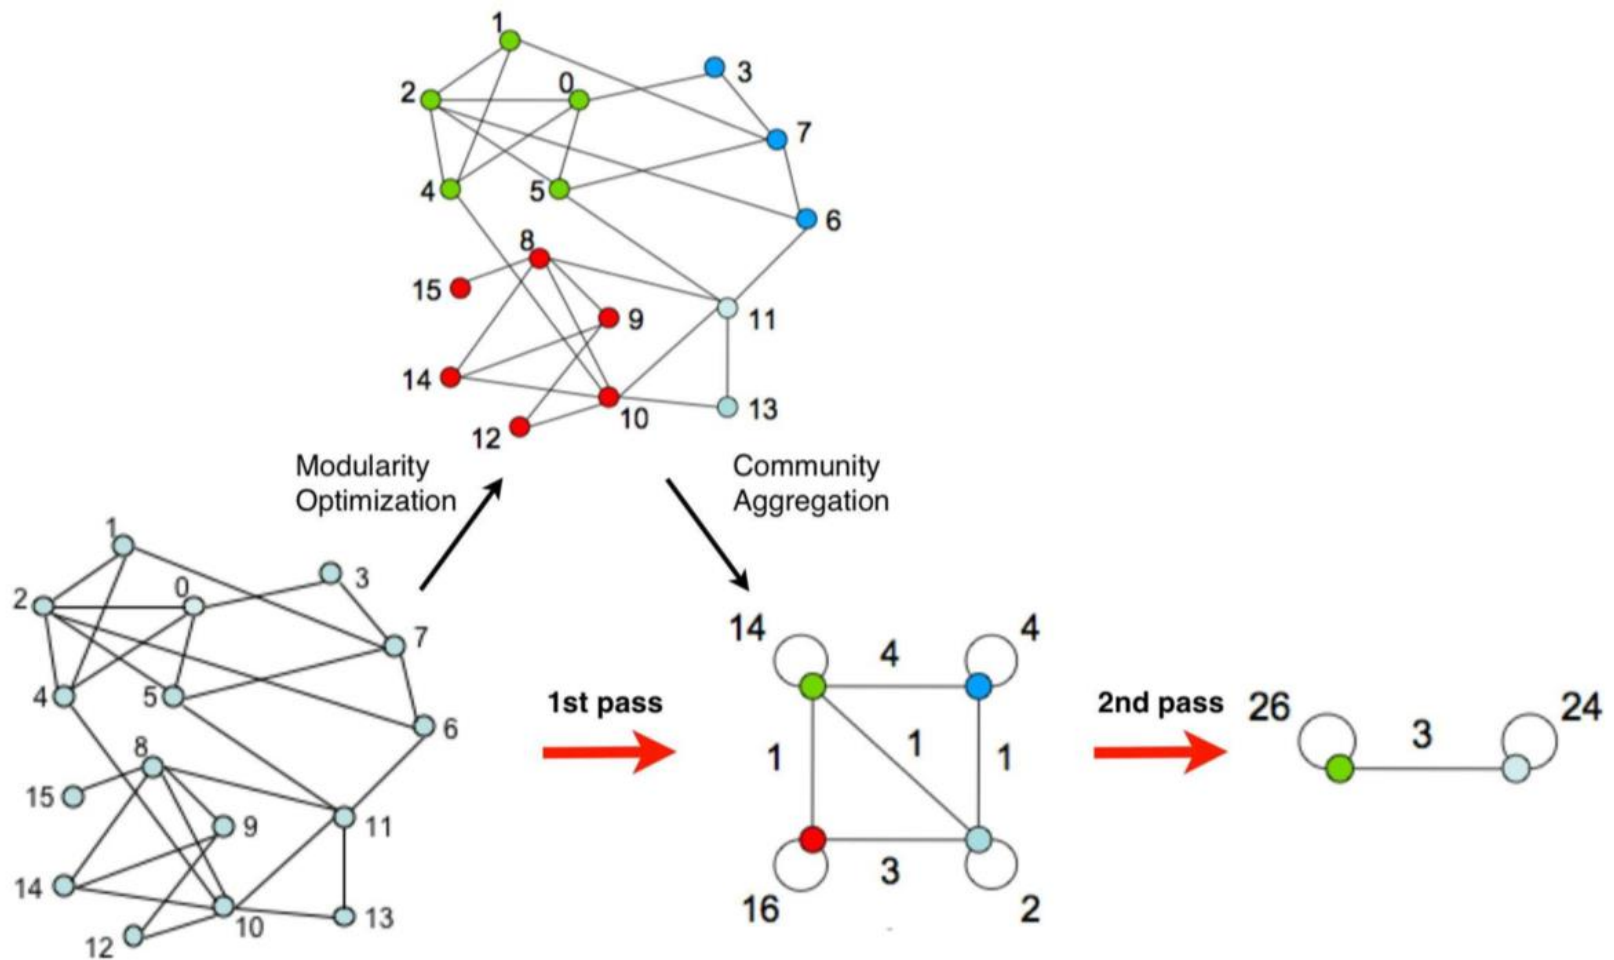

```

18 // Calculate community set and modularity.
19  $Q \leftarrow 0$ ;
20 for  $c \in C$  do
21    $Q \leftarrow Q + \frac{\Sigma_{in}^c}{2m} - (\frac{\Sigma_{tot}^c}{2m})^2$ ;
22    $C' \leftarrow \{c\}, \forall c \in C$ ; print  $C'$  and  $Q$ ;
23   // Phase 2: Rebuild Graph.
24    $V' \leftarrow C'$ ; Communities contracted into super-nodes
25    $E' \leftarrow \{e(c, c')\}, \exists e(u, v) \in E, u \in c, v \in c'$ ;
26    $w_{c, c'} \leftarrow \sum w_{u, v}, \forall e(u, v) \in E, u \in c, v \in c'$ ;
27   if No community changes then
28     exit outer Loop;
29    $V \leftarrow V'$ ;  $E \leftarrow E'$ ; Halting criterion
                                     for 2nd Phase

```

the weights of the edges between the new super-nodes are given by the **sum of the weights of the edges** between vertices in the corresponding two communities

# Louvain Algorithm

# Belgian Mobile phone network

- 2M nodes
- Red nodes: French speakers
- Green nodes: Dutch speakers

# Summary: Modularity

- **Modularity:**

- Overall quality of the partitioning of a graph into communities
- Used to determine the number of communities

- **Louvain modularity maximization:**

- Greedy strategy
- Great performance, scales to large networks
