Seven Bridges of Königsberg

[Euler, 1735]

Return to the starting point by traveling each link of the graph once and only once.

Web as a Graph

Web as a directed graph:

- Nodes: Webpages
- Edges: Hyperlinks

I teach a class on Networks.

CS224W: Classes are in the Gates building

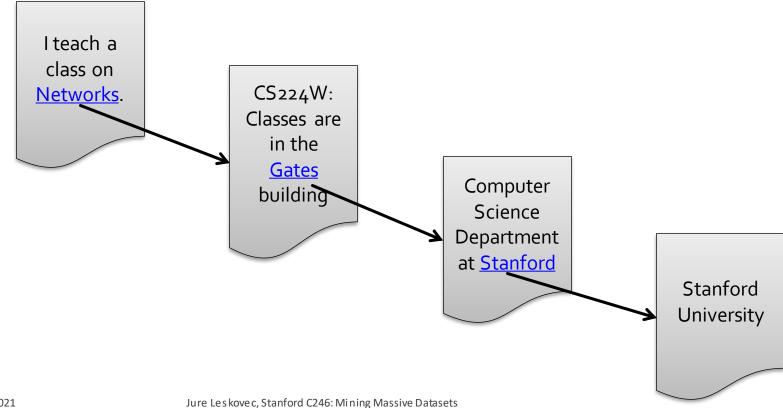

Computer Science Department at Stanford

> Stanford University

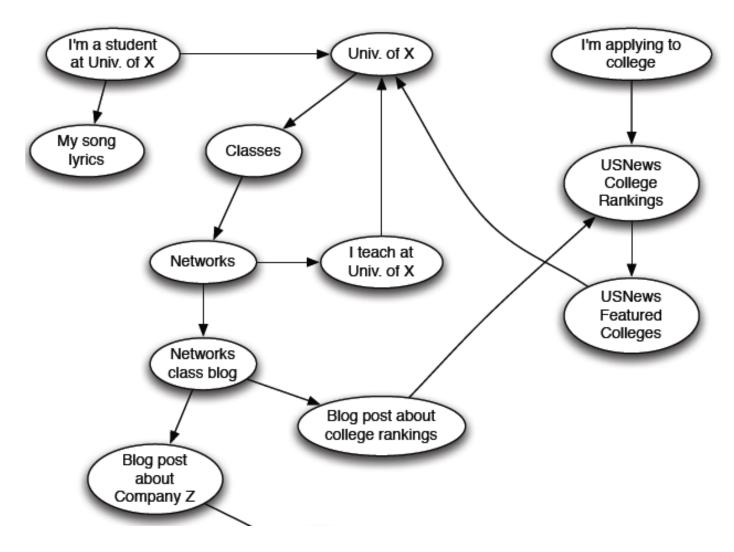

Web as a Graph

Web as a directed graph:

- Nodes: Webpages
- Edges: Hyperlinks

Web as a Directed Graph

Broad Question

- Property of the Property of
- First try: Human curated
 Web directories
 - Yahoo, DMOZ, LookSmart
- Second try: Web Search
 - Information Retrieval investigates: Find relevant docs in a small and trusted set
 - Newspaper articles, Patents, etc.
 - But: Web is huge, full of untrusted documents, random things, web spam, etc.

Web Search: 2 Challenges

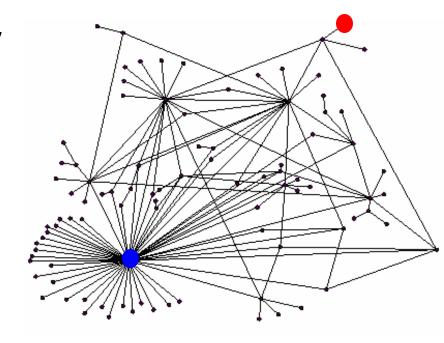

- 2 challenges of web search:
- (1) Web contains many sources of information Who to "trust"?
 - Trick: Trustworthy pages may point to each other!
- (2) What is the "best" answer to query "newspaper"?
 - No single right answer
 - Trick: Pages that actually know about newspapers might all be pointing to many newspapers

Ranking Nodes on the Graph

2 All web pages are not equally "important"

thispersondoesnotexist.com vs. www.stanford.edu

There is a large diversity in the web-graph node connectivity.
Let's rank the pages by the link structure!

Link Analysis Algorithms

- We will cover the following Link Analysis approaches for computing importance of nodes in a graph:
 - PageRank
 - Topic-Specific (Personalized) PageRank
 - Web Spam Detection Algorithms

PageRank: The "Flow" Formulation

Links as Votes

- Idea: Links as votes
 - Page is more important if it has more links
 - In-coming links? Out-going links?
- Think of in-links as votes:
 - www.stanford.edu has millions in-links
 - thispersondoesnotexist.com has a few thousands in-link
- Are all in-links equal?
 - Links from important pages count more
 - Recursive question!

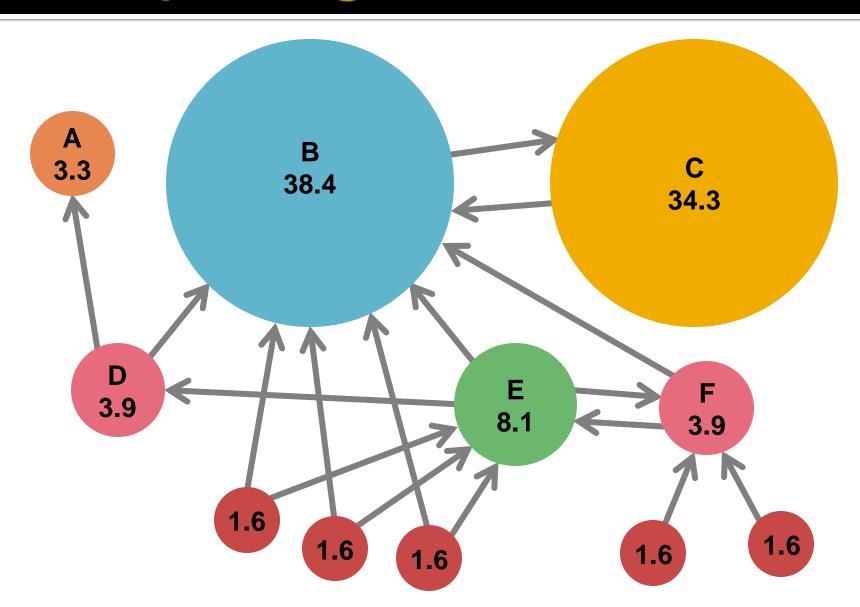

Intuition — (1)

- Web pages are important if people visit them a lot.
- But we can't watch everybody using the Web.
- A good surrogate for visiting pages is to assume people follow links randomly.
- Leads to random surfer model:
 - Start at a random page and follow random outlinks repeatedly, from whatever page you are at.
 - PageRank = limiting probability of being at a page.

Intuition - (2)

- Solve the recursive equation: "importance of a page = its share of the importance of each of its predecessor pages"
 - Equivalent to the random-surfer definition of PageRank
- Technically, importance = the principal eigenvector of the transition matrix of the Web
 - A few fix-ups needed

Example: PageRank Scores

Simple Recursive Formulation

- Each link's vote is proportional to the importance of its source page
- If page j with importance r_i has n out-links, each link gets r_i / n votes
- Page j's own importance is the sum of the votes on its in-links

$$r_j = r_i/3 + r_k/4$$

$$r_{ij/3}$$

$$r_{ij/3}$$

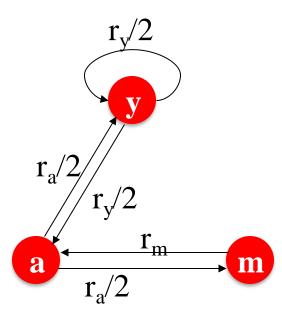

PageRank: The "Flow" Model

- A "vote" from an important page is worth more
- A page is important if it is pointed to by other important pages
- Property of the image of the image i is a parameter of the image of

$$r_j = \sum_{i \to j} \frac{r_i}{d_i}$$

 d_i ... out-degree of node i

The web in 1839

"Flow" equations:

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2 + \mathbf{r}_{m}$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2$$

Solving the Flow Equations

- 3 equations, 3 unknowns, no constants
 - No unique solution

- Flow equations: $\mathbf{r}_y = \mathbf{r}_y/2 + \mathbf{r}_a/2$ $\mathbf{r}_a = \mathbf{r}_y/2 + \mathbf{r}_m$ $\mathbf{r}_m = \mathbf{r}_a/2$
- All solutions equivalent modulo the scale factor
- Additional constraint forces uniqueness:

$$r_y + r_a + r_m = 1$$

• Solution:
$$r_y = \frac{2}{5}$$
, $r_a = \frac{2}{5}$, $r_m = \frac{1}{5}$

- Gaussian elimination method works for small examples, but we need a better method for large web-size graphs
- We need a new formulation!

PageRank: Matrix Formulation

Stochastic adjacency matrix M

- Let page i has d_i out-links
- If $i \rightarrow j$, then $M_{ji} = \frac{1}{d_i}$ else $M_{ji} = 0$
 - M is a column stochastic matrix
 - Columns sum to 1
- Rank vector r: vector with an entry per page
 - $lacktriangleright r_i$ is the importance score of page i
- The flow equations can be written

$$r = M \cdot r$$

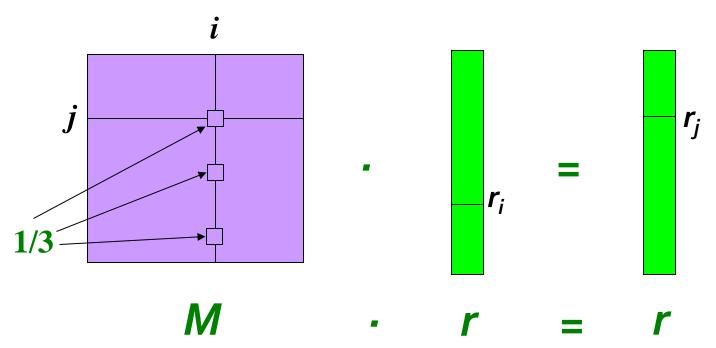

$$r_j = \sum_{i \to j} \frac{r_i}{d_i}$$

Example

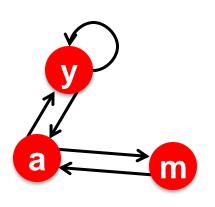

Remember the flow equation: $r_j = \sum_{i \to j} \frac{r_i}{d_i}$ Plow equation in the matrix form

$$M \cdot r = r$$

Suppose page i links to 3 pages, including j

Example: Flow Equations & M

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2 + \mathbf{r}_{m}$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2$$

	$\mathbf{r}_{\mathbf{y}}$	r _a	r _m
ry	1/2	1/2	0
ra	1/2	0	1
$\mathbf{r}_{\mathbf{m}}$	0	1/2	0

$$r = M \cdot r$$

$$\begin{vmatrix} r_y \\ r_a \\ r_m \end{vmatrix} = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & 0 & 1 \\ 0 & \frac{1}{2} & 0 \end{vmatrix} \begin{vmatrix} r_y \\ r_a \\ r_m \end{vmatrix}$$

Eigenvector Formulation

The flow equations can be written

$$r = M \cdot r$$

- So the rank vector r is an eigenvector of the stochastic web matrix M
 - Starting from any stochastic vector u, the limit M(M(...M(Mu))) is the long-term distribution of the surfers.
 - The math: limiting distribution = principal eigenvector of M = PageRank.
 - Note: If r is the limit of $MM \dots Mu$, then r satisfies the equation r = Mr, so r is an eigenvector of M with eigenvalue 1
- We can now efficiently solve for r!
 The method is called Power iteration

NOTE: x is an eigenvector with the corresponding eigenvalue λ if:

$$Ax = \lambda x$$

Power Iteration Method

- Given a web graph with N nodes, where the nodes are pages and edges are hyperlinks
- Power iteration: a simple iterative scheme
 - Suppose there are N web pages
 - Initialize: $\mathbf{r}^{(0)} = [1/N,....,1/N]^T$
 - Iterate: $\mathbf{r}^{(t+1)} = \mathbf{M} \cdot \mathbf{r}^{(t)}$
 - Stop when $|\mathbf{r}^{(t+1)} \mathbf{r}^{(t)}|_1 < \varepsilon$

 $|\mathbf{x}|_1 = \sum_{1 \le i \le N} |x_i|$ is the **L**₁ norm Can use any other vector norm, e.g., Euclidean

$$r_j^{(t+1)} = \sum_{i \to j} \frac{r_i^{(t)}}{d_i}$$

d_i out-degree of node i

About 50 iterations is sufficient to estimate the limiting solution.

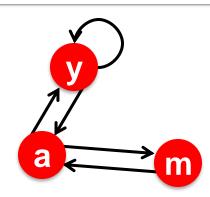

PageRank: How to solve?

Power Iteration:

- Set $r_j = 1/N$
- 1: $r'_j = \sum_{i \to j} \frac{r_i}{d_i}$
- 2: r = r'
- Goto 1

Example:

Iteration 0, 1, 2, ...

	y	a	m
y	1/2	1/2	0
a	1/2	0	1
m	0	1/2	0

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

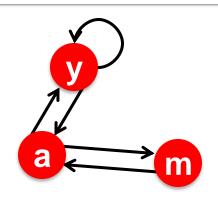

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2 + \mathbf{r}_{m}$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2$$

PageRank: How to solve?

Power Iteration:

- Set $r_j = 1/N$
- 1: $r'_j = \sum_{i \to j} \frac{r_i}{d_i}$
- 2: r = r'
- Goto 1

	y	a	m
y	1/2	1/2	0
a	1/2	0	1
m	0	1/2	0

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2 + \mathbf{r}_{m}$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2$$

Example:

$$\begin{bmatrix} r_y \\ r_a \\ r_m \end{bmatrix} = \begin{array}{ccccc} 1/3 & 1/3 & 5/12 & 9/24 & 6/15 \\ 1/3 & 3/6 & 1/3 & 11/24 & \dots & 6/15 \\ 1/3 & 1/6 & 3/12 & 1/6 & 3/15 \\ \end{array}$$

Iteration 0, 1, 2, ...

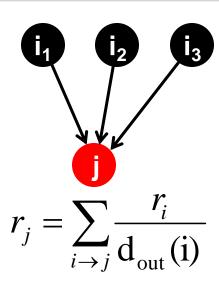

Random Walk Interpretation

Imagine a random web surfer:

- At any time t, surfer is on some page i
- At time t + 1, the surfer follows an out-link from i uniformly at random
- Ends up on some page j linked from i
- Process repeats indefinitely

? Let:

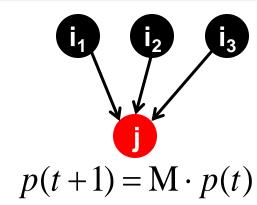

- p(t) ... vector whose i^{th} coordinate is the prob. that the surfer is at page i at time t
- lacksquare So, $m{p}(m{t})$ is a probability distribution over pages

The Stationary Distribution

? Where is the surfer at time t+1?

Follows a link uniformly at random $p(t+1) = M \cdot p(t)$

Suppose the random walk reaches a state

$$p(t+1) = M \cdot p(t) = p(t)$$

then $oldsymbol{p(t)}$ is stationary distribution of a random walk

- Our original rank vector r satisfies $r = M \cdot r$
 - So, r is a stationary distribution for the random walk

Existence and Uniqueness

A central result from the theory of random walks (a.k.a. Markov processes):

For graphs that satisfy **certain conditions**, the **stationary distribution is unique** and eventually will be reached no matter what is the initial probability distribution at time **t** = **0**

PageRank for Undirected Graphs

- Given an <u>undirected</u> graph with N nodes, where the nodes are pages and edges are hyperlinks
 - X Y Z

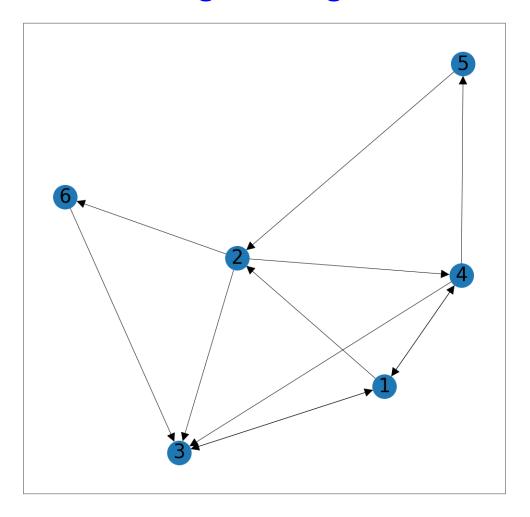

- Claim [Existence]: For node v, $r_v = d_v/2m$ is a solution.
- Proof:
 - Iteration step: $\mathbf{r}^{(t+1)} = \mathbf{M} \cdot \mathbf{r}^{(t)}$
 - Substitute $r_i = d_i/2m$:

 $r_v^{(t+1)} = \frac{r_x^t}{d_x} + \frac{r_y^t}{d_y} + \frac{r_z^t}{d_z}$ $r_v^{(t+1)} = \frac{3}{2m}$

Done! Uniqueness: exercise! m = #edges

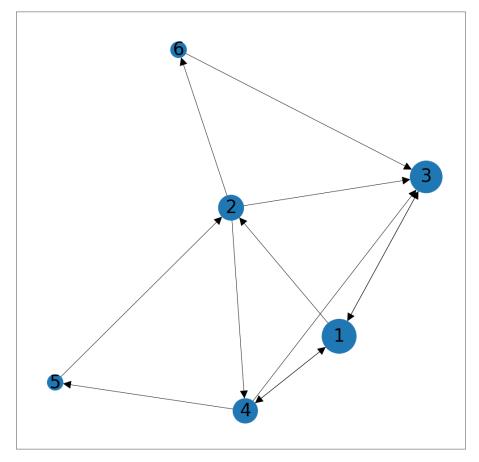

PageRank: test your intuition 1

Which node has highest PageRank? Second highest?

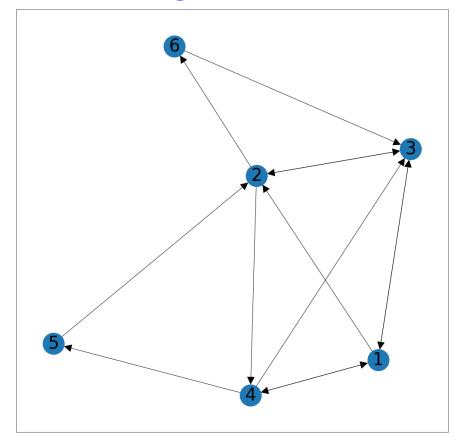

PageRank: test your intuition 1

- Node 1 has the highest PR, followed by Node 3
- Degree ≠ PageRank

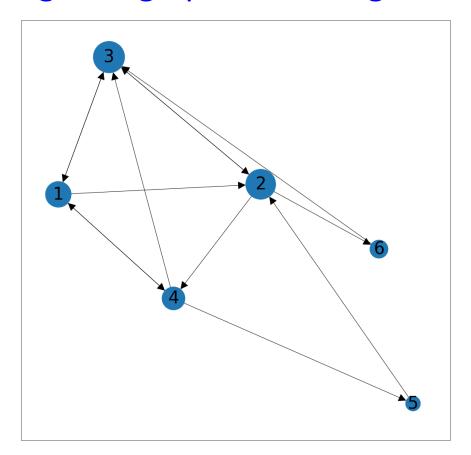

PageRank: test your intuition 2

Add edge 3 -> 2. Now, which node has highest PageRank? Second highest?

PageRank: test your intuition 2

- Node 3 has the highest PR, followed by 2.
- Small changes to graph can change PR!

PageRank: The Google Formulation

PageRank: Three Questions

$$r_j^{(t+1)} = \sum_{i \to j} \frac{r_i^{(t)}}{d_i}$$
 or equivalently $r = Mr$

- Does this converge?
- Does it converge to what we want?
- Are results reasonable?

Does this converge?

$$r_j^{(t+1)} = \sum_{i \to j} \frac{r_i^{(t)}}{d_i}$$

Example:

Does it converge to what we want?

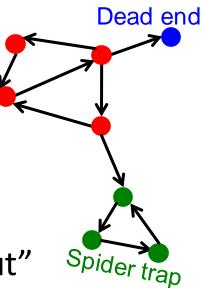

$$r_j^{(t+1)} = \sum_{i \to j} \frac{r_i^{(t)}}{d_i}$$

Example:

PageRank: Problems

Two problems:

- (1) Dead ends: Some pages have no out-links
 - Random walk has "nowhere" to go to
 - Such pages cause importance to "leak out"

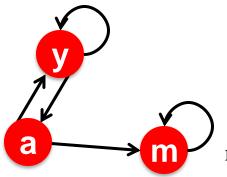

- (2) Spider traps:
 - (all out-links are within the group)
 - Random walk gets "stuck" in a trap
 - And eventually spider traps absorb all importance

Problem: Spider Traps

Power Iteration:

- Set $r_i = 1/N$
- $r_j = \sum_{i \to j} \frac{r_i}{d_i}$
 - And iterate

	y	a	m
y	1/2	1/2	0
a	1/2	0	0
m	0	1/2	1

m is a spider trap

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2 + \mathbf{r}_{m}$$

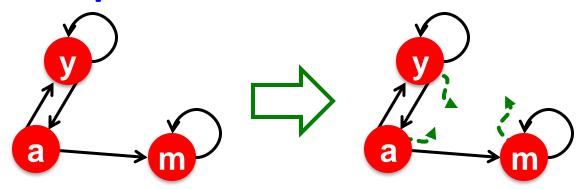

Example:

Iteration 0, 1, 2, ...

All the PageRank score gets "trapped" in node m.

Solution: Teleports!

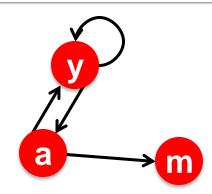

- The Google solution for spider traps: At each time step, the random surfer has two options
 - With prob. β , follow a link at random
 - With prob. **1-** β , jump to some random page
 - β is typically in the range 0.8 to 0.9
- Surfer will teleport out of spider trap within a few time steps

Problem: Dead Ends

Power Iteration:

- Set $r_j = 1/N$
- $r_j = \sum_{i \to j} \frac{r_i}{d_i}$
 - And iterate

	y	a	m
y	1/2	1/2	0
a	1/2	0	0
m	0	1/2	0

$$\mathbf{r}_{y} = \mathbf{r}_{y}/2 + \mathbf{r}_{a}/2$$

$$\mathbf{r}_{a} = \mathbf{r}_{y}/2$$

$$\mathbf{r}_{m} = \mathbf{r}_{a}/2$$

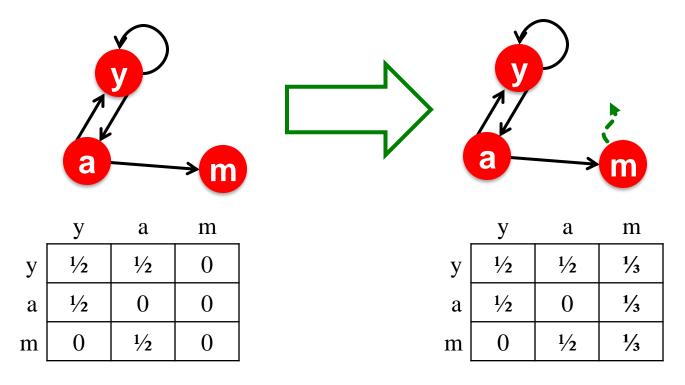

Example:

Iteration 0, 1, 2, ...

Here the PageRank score "leaks" out since the matrix is not stochastic.

Solution: Always Teleport!

- Teleports: Follow random teleport links with probability 1.0 from dead-ends
 - Adjust matrix accordingly

Why Teleports Solve the Problem?

Why are dead-ends and spider traps a problem and why do teleports solve the problem?

- Spider-traps are not a problem, but with traps PageRank scores are not what we want
 - Solution: Never get stuck in a spider trap by teleporting out of it in a finite number of steps
- Dead-ends are a problem
 - The matrix is not column stochastic so our initial assumptions are not met
 - Solution: Make matrix column stochastic by always teleporting when there is nowhere else to go

Solution: Random Teleports

Google's solution that does it all:

At each step, random surfer has two options:

- With probability β , follow a link at random
- With probability $1-\beta$, jump to some random page
- PageRank equation [Brin-Page, 98]

$$r_j = \sum_{i o j} eta \; rac{r_i}{d_i} + (1 - eta) rac{1}{N}$$
 d_i... out-degree of node i

This formulation assumes that *M* has no dead ends. We can either preprocess matrix *M* to remove all dead ends or explicitly follow random teleport links with probability 1.0 from dead-ends.

The Google Matrix

PageRank equation [Brin-Page, '98]

$$r_j = \sum_{i \to j} \beta \frac{r_i}{d_i} + (1 - \beta) \frac{1}{N}$$

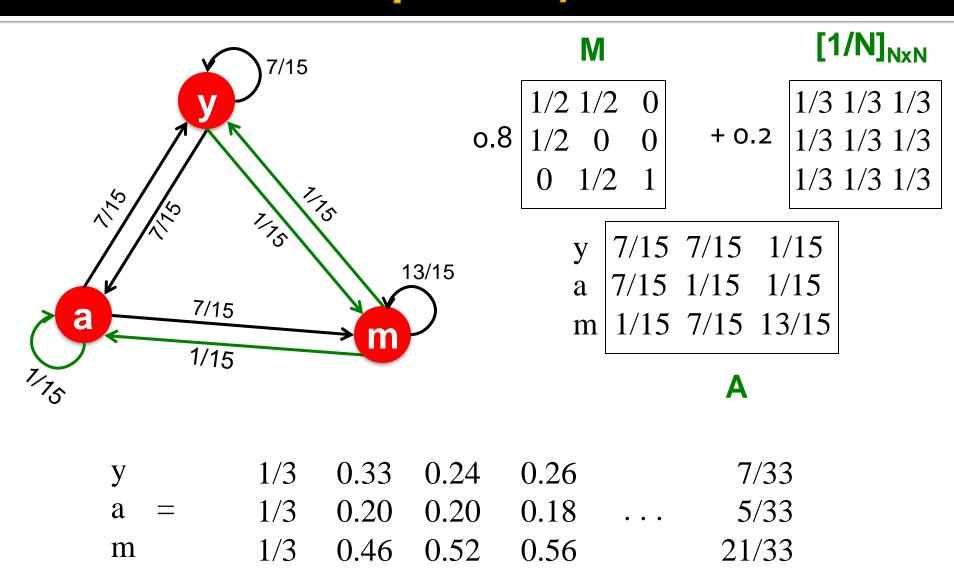

The Google Matrix A:

 $[1/N]_{NxN}...N$ by N matrix where all entries are 1/N

$$A = \beta M + (1 - \beta) \left[\frac{1}{N} \right]_{N \times N}$$

- **We have a recursive problem:** $r = A \cdot r$ And the Power method still works!
- - In practice $\beta = 0.8, 0.9$ (jump every 5 steps on avg.)

Random Teleports ($\beta = 0.8$)

How do we actually compute the PageRank?

Computing PageRank

Rey step is matrix-vector multiplication

- $r^{\text{new}} = A \cdot r^{\text{old}}$
- Easy if we have enough main memory to hold A, r^{old}, r^{new}
- Say N = 1 billion pages
 - We need 4 bytes for each entry (say)
 - 2 billion entries for vectors, approx 8GB
 - Matrix A has N² entries
 - 10¹⁸ is a large number!

$$\mathbf{A} = \beta \cdot \mathbf{M} + (\mathbf{1} - \beta) \left[\mathbf{1} / \mathbf{N} \right]_{\mathbf{N} \times \mathbf{N}}$$

$$\mathbf{A} = 0.8 \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & 1 \end{bmatrix} + 0.2 \begin{bmatrix} \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{bmatrix}$$

Rearranging the Equation

$$\begin{array}{ll} ? \ r &= A \cdot r, \ \text{ where } A_{ji} = \beta \ M_{ji} + \frac{1-\beta}{N} \\ ? \ r_{j} &= \sum_{i=1}^{N} A_{ji} \cdot r_{i} \\ ? \ r_{j} &= \sum_{i=1}^{N} \left[\beta \ M_{ji} + \frac{1-\beta}{N}\right] \cdot r_{i} \\ &= \sum_{i=1}^{N} \beta \ M_{ji} \cdot r_{i} + \frac{1-\beta}{N} \sum_{i=1}^{N} r_{i} \\ &= \sum_{i=1}^{N} \beta \ M_{ji} \cdot r_{i} + \frac{1-\beta}{N} \quad \text{since } \sum r_{i} = 1 \\ ? \ \text{So we get: } r &= \beta \ M \cdot r + \left[\frac{1-\beta}{N}\right]_{N} \end{array}$$

Note: Here we assume **M** has no dead-ends

 $[x]_N$... a vector of length N with all entries x

Sparse Matrix Formulation

We just rearranged the PageRank equation

$$r = \beta M \cdot r + \left[\frac{1-\beta}{N}\right]_N$$

- where $[(1-\beta)/N]_N$ is a vector with all **N** entries $(1-\beta)/N$
- M is a sparse matrix! (with no dead-ends)
 - 10 links per node, approx 10N entries
- So in each iteration, we need to:
 - Compute $r^{\text{new}} = \beta M \cdot r^{\text{old}}$
 - Add a constant value $(1-\beta)/N$ to each entry in r^{new}
 - Note if M contains dead-ends then $\sum_j r_j^{new} < 1$ and we also have to renormalize r^{new} so that it sums to 1

PageRank: The Complete Algorithm

Input: Graph G and parameter β

- Directed graph G (can have spider traps and dead ends)
- Parameter β
- Output: PageRank vector r^{new}
 - **Set:** $r_j^{old} = \frac{1}{N}$
 - repeat until convergence: $\sum_{j} |r_{j}^{new} r_{j}^{old}| < \varepsilon$
 - $\forall j: \ r'^{new}_j = \sum_{i \to j} \beta \ \frac{r^{old}_i}{d_i}$ $r'^{new}_j = \mathbf{0} \ \text{if in-degree of } \mathbf{j} \text{ is } \mathbf{0}$
 - Now re-insert the leaked PageRank:

$$\forall j: r_j^{new} = r_j^{new} + \frac{1-S}{N} \text{ where: } S = \sum_j r_j^{new}$$

$$r^{old} = r^{new}$$

If the graph has no dead-ends then the amount of leaked PageRank is $1-\beta$. But since we have dead-ends the amount of leaked PageRank may be larger. We have to explicitly account for it by computing S.

Sparse Matrix Encoding

- Encode sparse matrix using only nonzero entries
 - Space proportional roughly to number of links
 - Say 10N, or 4*10*1 billion = 40GB

COLLECA

Still won't fit in memory, but will fit on disk

node	degree	destination nodes
0	3	1, 5, 7
1	5	17, 64, 113, 117, 245
2	2	13, 23

Basic Algorithm: Update Step

- Assume enough RAM to fit r^{new} into memory
 - Store rold and matrix M on disk
- 1 step of power-iteration is:

```
Initialize all entries of \mathbf{r}^{\text{new}} = (1-\beta) / \mathbf{N}

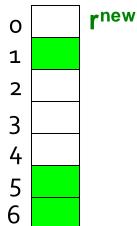

For each page i (of out-degree d_i):

Read into memory: i, d_i, dest_1, ..., dest_{di}, r^{old}(i)

For j = 1...d_i

r^{\text{new}}(dest_j) += \beta r^{\text{old}}(i) / d_i
```

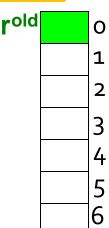

Assuming no dead ends

source	degree	destination
50 at 50	acgioc	acctiliation

Jure Les kovec, Stanford C246: Mining Massive Datasets

0	3	1, 5, 6
1	4	17, 64, 113, 117
2	2	13, 23

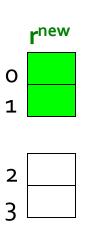

Analysis

- Assume enough RAM to fit r^{new} into memory
 - Store rold and matrix M on disk
- In each iteration, we have to:
 - Read r^{old} and M
 - Write r^{new} back to disk
 - Cost per iteration of Power method:

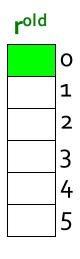

$$=2|r| + |M|$$

- Question:
 - What if we could not even fit r^{new} in memory?

Block-based Update Algorithm

src	degree	destination
0	4	0, 1, 3, 5
1	2	0, 5
2	2	3, 4
M		

- Break r^{new} into k blocks that fit in memory
- Scan M and rold once for each block

Analysis of Block Update

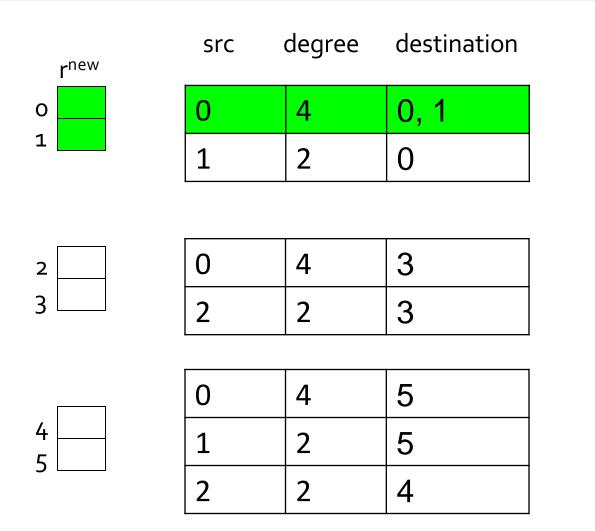

Similar to nested-loop join in databases

- Break r^{new} into k blocks that fit in memory
- Scan M and rold once for each block

Total cost:

- k scans of M and rold
- Cost per iteration of Power method: k(|M| + |r|) + |r| = k|M| + (k+1)|r|
- Can we do better?
 - Hint: M is much bigger than r (approx 10-20x), so we must avoid reading it k times per iteration

Block-Stripe Update Algorithm

r ^{old}	
	0
	1
	2
	3
	4
	5

Break *M* into stripes! Each stripe contains only destination nodes in the corresponding block of *r*^{new}

Block-Stripe Analysis

Break M into stripes

- Each stripe contains only destination nodes in the corresponding block of r^{new}
- Some additional overhead per stripe
 - But it is usually worth it
- Cost per iteration of Power method:

$$=|M|(1+\varepsilon) + (k+1)|r|$$

Some Problems with PageRank

Measures generic popularity of a page

- Biased against topic-specific authorities
- Solution: Topic-Specific PageRank (next)
- Uses a single measure of importance
 - Other models of importance
 - Solution: Hubs-and-Authorities
- Susceptible to Link spam
 - Artificial link topographies created in order to boost page rank
 - Solution: TrustRank

Historical note on Link Analysis

- Classic work: Markov chains, citation analysis
- RankDex patent [Robin Li, '96]
 - Key idea: use backlinks (led to Baidu!)
- HITS Algorithm [Kleinberg, SODA '98]
 - Key idea: iterative scoring!
